

**Welcome to**

# **Programming Massively Parallel Processors (PMPP)**

**Prof. Dr.-Ing. Michael Goesele**  
**Dr. Stefan Guthe**  
**Dominik Wodniok**

**Graphics, Capture and Massively Parallel Computing (GCC)**  
**TU Darmstadt**

# (Preliminary) Course Schedule

you are here

12.10.2015	Introduction to PMPP
13.10.2015	Lecture CUDA Programming 1
19.10.2015	Lecture CUDA Programming 2
20.10.2015	Lecture CUDA Programming 3
26.10.2015	Introduction Final Projects, Exercise 1 assigned
27.10.2015	Questions and Answers (Q&A)
2.11.2015	Lecture, Final Projects assigned, Ex. 1 due, Ex. 2 assigned
3.11.2015	Questions and Answers (Q&A)
9.11.2015	Lecture, Exercise 2 due
10.11.2015	Lecture
16.11.2015	Questions and Answers (Q&A)
17.11.2015	Questions and Answers (Q&A)
23.11.2015	1 <sup>st</sup> Status Presentation Final Projects
24.11.2015	1 <sup>st</sup> Status Presentation Final Projects (continued)
30.11.2015	
1.12.2015	

# Registering in TuCAN/Moodle

---

- | in TuCAN, you can register for a module and for a course within the module
- | only if you did both, you are actually registered for the course and automatically receive a Moodle account!
- | If you still haven't signed the HHLR account request, please do so *now*

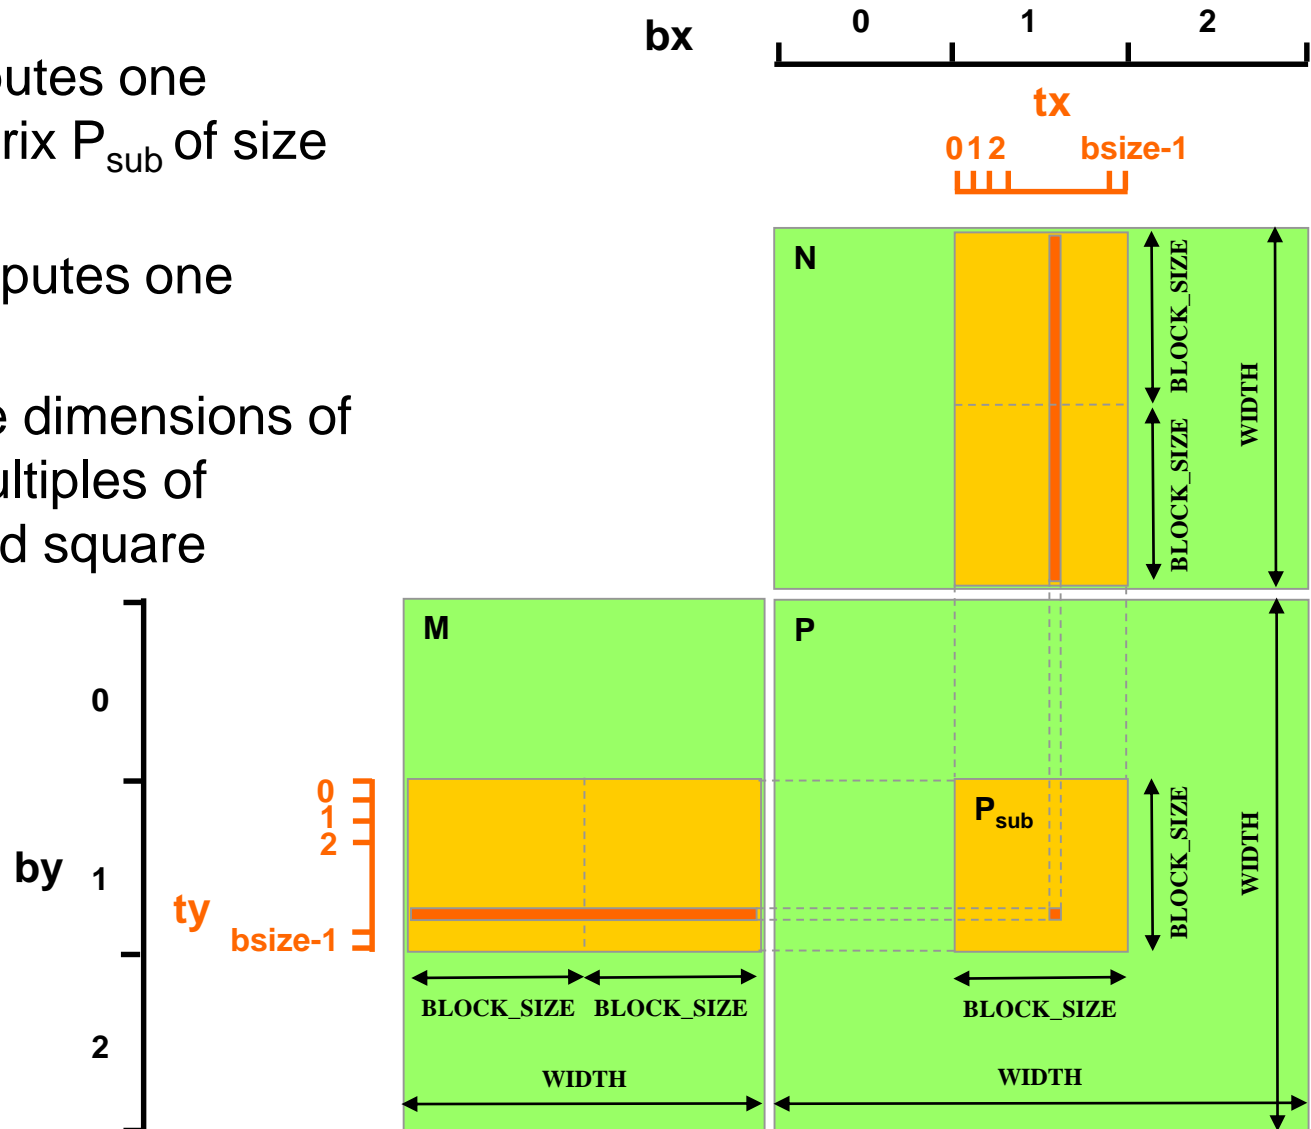

# Today's Topics

---

- | refresher from last lecture: extension of simple matrix multiplication example to incorporate shared memory
- | fast memory access
  - | bank conflicts in shared memory
  - | memory coalescing for global memory
- | control flow
  - | avoiding divergence
- | example: vector reduction

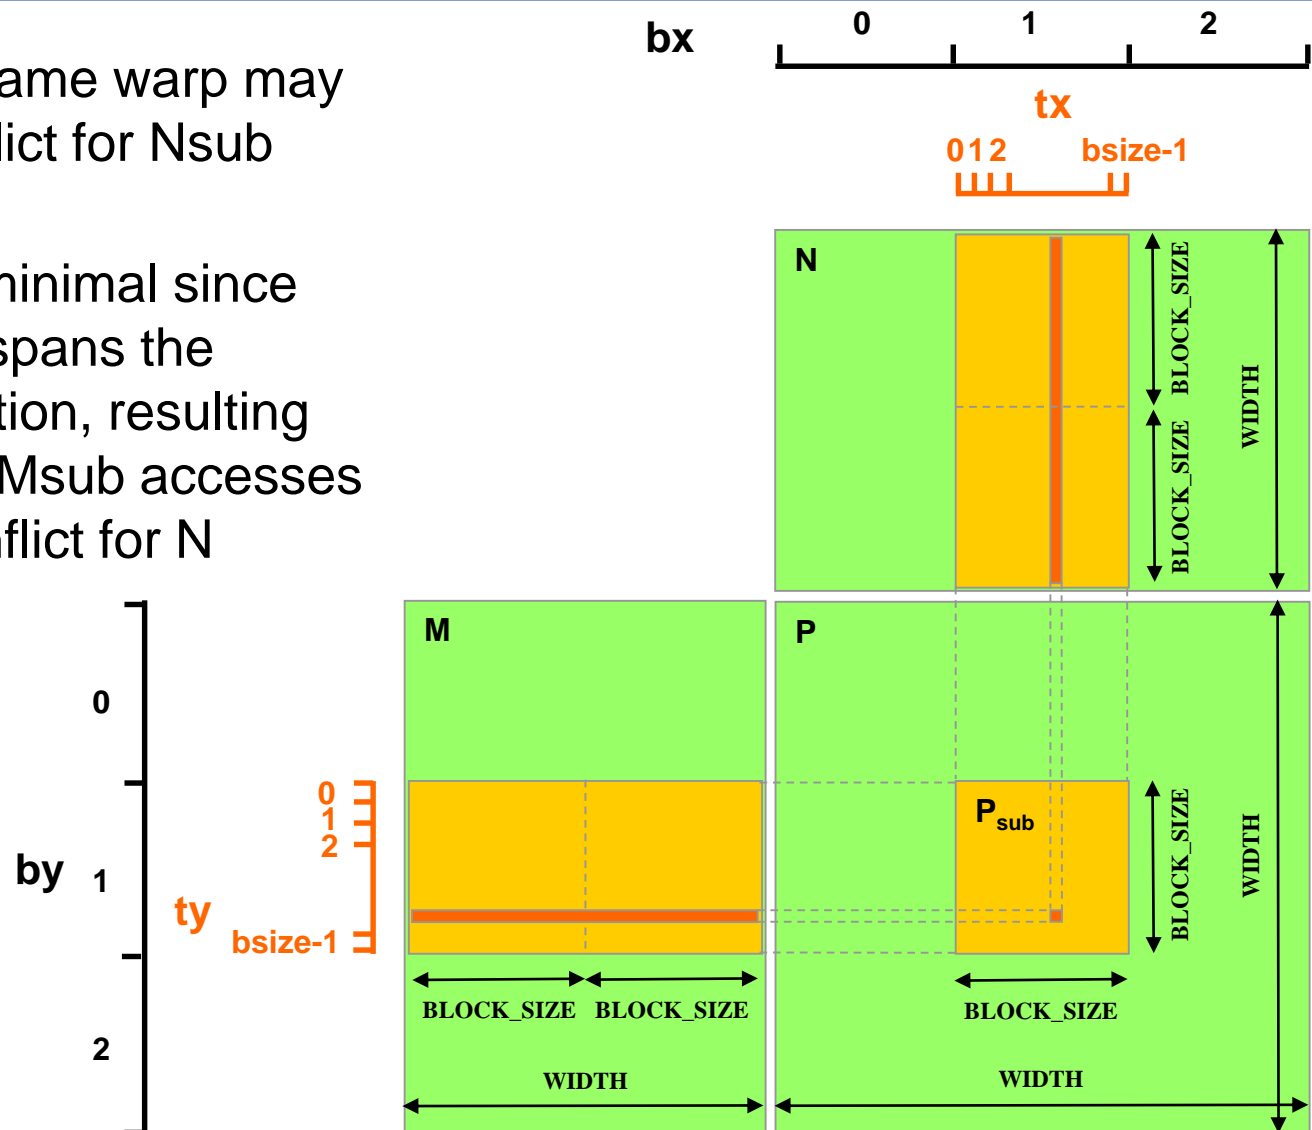

# Tiled Multiply Using Thread Blocks

- | one **block** computes one square sub-matrix  $P_{\text{sub}}$  of size  $\text{BLOCK\_SIZE}$
- | one **thread** computes one element of  $P_{\text{sub}}$
- | assume that the dimensions of  $M$  and  $N$  are multiples of  $\text{BLOCK\_SIZE}$  and square shape

# Shared Memory Bank Conflicts

- threads in the same warp may have bank conflict for  $N_{\text{sub}}$  accesses
- this should be minimal since the warp likely spans the horizontal direction, resulting in broadcast of  $M_{\text{sub}}$  accesses and no/little conflict for  $N$  accesses

- | GPUs can be categorized into different classes according to their capabilities
- | compute capability
  - | major distinction between hardware architectures
  - | 1.x (1.0, 1.1, 1.2, 1.3) **NOT SUPPORTED ANYMORE!**
  - | 2.x (2.0, 2.1) for Fermi architecture
  - | 3.x (3.0, 3.5, 3.7) for Kepler architecture
  - | 5.x (5.0, 5.2, 5.3) for Maxwell architecture
- | see details on the next slides and in the CUDA C Programming Guide
- | requires different optimizations for different GPU generations

# CUDA Compute Capabilities

Feature Support	Compute Capability				
	2.x	3.0	3.2	3.5, 3.7, 5.0, 5.2	5.3
<b>(Unlisted features are supported for all compute capabilities)</b>					
Atomic functions operating on 32-bit integer values in global memory ( <a href="#">Atomic Functions</a> )					
atomicExch() operating on 32-bit floating point values in global memory ( <a href="#">atomicExch()</a> )					
Atomic functions operating on 32-bit integer values in shared memory ( <a href="#">Atomic Functions</a> )					
atomicExch() operating on 32-bit floating point values in shared memory ( <a href="#">atomicExch()</a> )					
Atomic functions operating on 64-bit integer values in global memory ( <a href="#">Atomic Functions</a> )					
Warp vote functions ( <a href="#">Warp Vote Functions</a> )					
Double-precision floating-point numbers					
Atomic functions operating on 64-bit integer values in shared memory ( <a href="#">Atomic Functions</a> )	Yes				
Atomic addition operating on 32-bit floating point values in global and shared memory ( <a href="#">atomicAdd()</a> )					
__ballot() ( <a href="#">Warp Vote Functions</a> )					
__threadfence_system() ( <a href="#">Memory Fence Functions</a> )					
__syncthreads_count(), __syncthreads_and(), __syncthreads_or() ( <a href="#">Synchronization Functions</a> )					
Surface functions ( <a href="#">Surface Functions</a> )					
3D grid of thread blocks					
Unified Memory Programming	No	Yes			
Funnel shift (see reference manual)	No		Yes		
Dynamic Parallelism	No			Yes	
Half-precision floating-point operations: addition, subtraction, multiplication, comparison, warp shuffle functions, conversion	No				Yes

# CUDA Compute Capabilities

	Compute Capability							
Technical Specifications	2.x	3.0	3.2	3.5	3.7	5.0	5.2	5.3
Maximum number of resident grids per device ( <a href="#">Concurrent Kernel Execution</a> )	16		4	32				16
Maximum dimensionality of grid of thread blocks	3							
Maximum x-dimension of a grid of thread blocks	65535	$2^{31}-1$						
Maximum y- or z-dimension of a grid of thread blocks	65535							
Maximum dimensionality of thread block	3							
Maximum x- or y-dimension of a block	1024							
Maximum z-dimension of a block	64							
Maximum number of threads per block	1024							
Warp size	32							
Maximum number of resident blocks per multiprocessor	8	16				32		
Maximum number of resident warps per multiprocessor	48	64						
Maximum number of resident threads per multiprocessor	1536	2048						
Number of 32-bit registers per multiprocessor	32 K	64 K			128 K	64 K		
Maximum number of 32-bit registers per thread block	32 K	64 K						32 K
Maximum number of 32-bit registers per thread	63		255					
Maximum amount of shared memory per multiprocessor	48 KB				112 KB	64 KB	96 KB	64 KB
Maximum amount of shared memory per thread block	48 KB							
Number of shared memory banks	32							
Amount of local memory per thread	512 KB							
Constant memory size	64 KB							
Cache working set per multiprocessor for constant memory	8 KB					10 KB		
Cache working set per multiprocessor for texture memory	12 KB	Between 12 KB and 48 KB						
Maximum width for a 1D texture reference bound to a CUDA array	65536							
Maximum width for a 1D texture reference bound to linear	$2^{27}$

Tesla K20X	14	2688	Geforce GTX 850M	5	640

\* 1152 for compute 3.0 (Kepler) or 640 for compute 5.0 (Maxwell) depending on the actual chip in the card (re-branding!)

# Parallel Memory Access

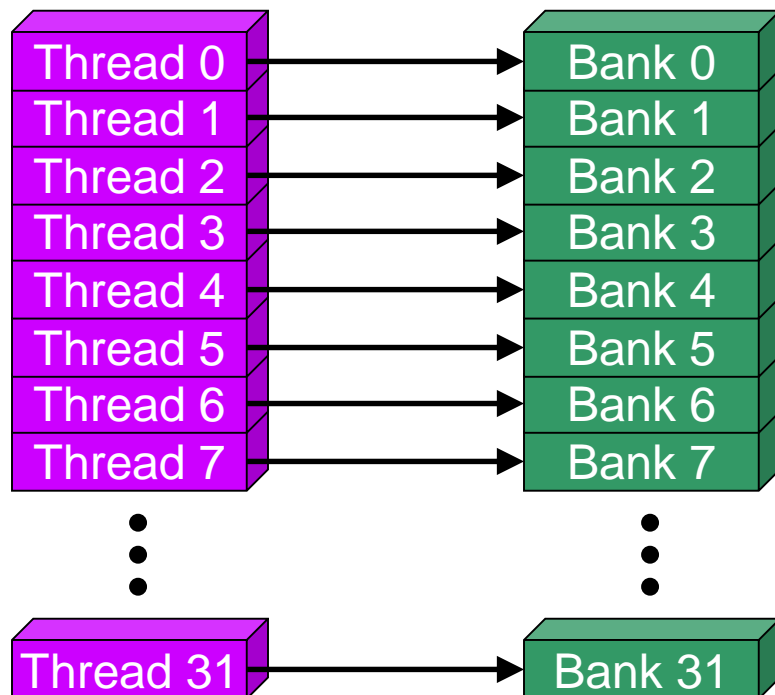

- | in a parallel machine, many threads access memory
  - | therefore, memory is divided into **banks**
  - | essential to achieve high bandwidth
- | each bank can service one address per cycle
  - | a memory can service as many simultaneous accesses as it has banks
- | multiple simultaneous accesses to a bank result in a **bank conflict**
  - | conflicting accesses are serialized

# Bank Addressing Examples

- | linear addressing with stride == 1

➔ no bank conflicts

- | random 1:1 permutation

- | each thread accesses unique bank

➔ no bank conflicts

# Bank Addressing Examples

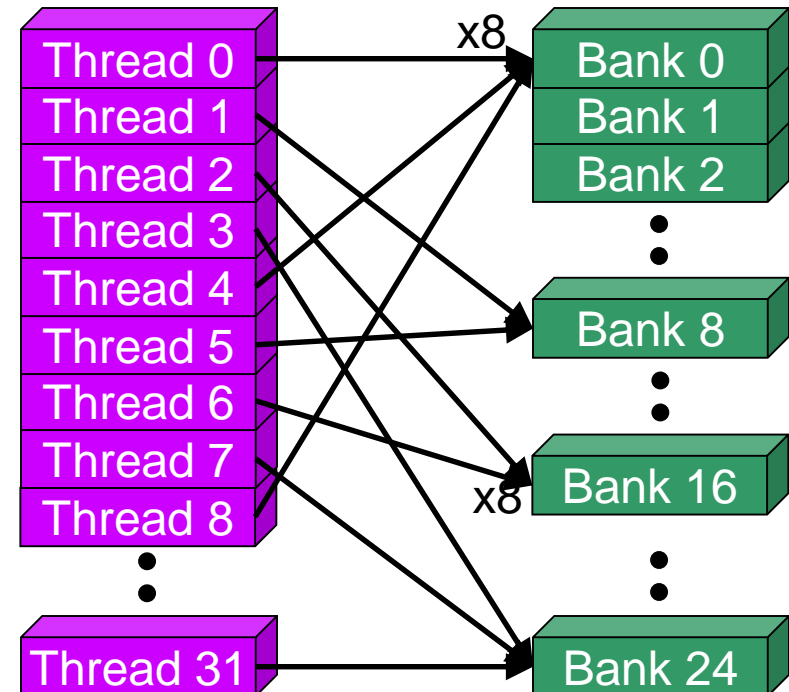

| linear addressing with  
stride == 2

➔ 2 way bank conflicts

| linear addressing with  
stride == 8

➔ 8 way bank conflicts

# How Addresses Map to Banks

- | each bank has a bandwidth of 32 bits per clock cycle
  - | e.g. 1 float
- | successive 32 bit words are assigned to successive banks
  - | additional 64 bit mode<sub>3.x</sub>
- | current hardware has 32 banks (compute capability 2.x and up)
  - | so bank = address (in 32 bits) % 32
  - | same as the size of a warp

- | the fast cases
  - | if all threads of a warp **access different banks**, there is no bank conflict
  - | if subgroups of warp threads **access the identical bank AND address**, there is no bank conflict (multicast)
- | the slow case
  - | multiple threads in the same warp access the same bank but different addresses
    - ➔ bank conflict
  - | must serialize the accesses
  - | cost = max # of simultaneous accesses to a single bank
- | shared memory is said to be as fast as registers if there are no bank conflicts

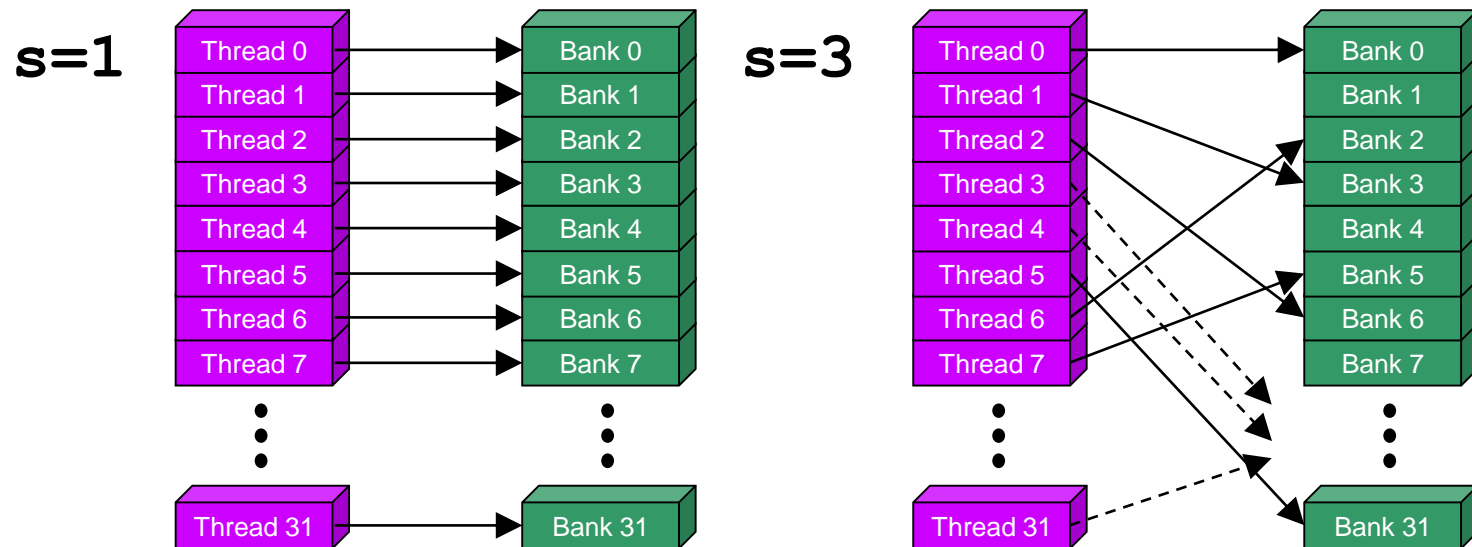

# Linear Addressing

```
__shared__ float shared[256];  
float foo = shared[baseIndex + s * threadIdx.x];
```

| this is only bank-conflict-free if  $s$  shares no common factors with the number of banks

| 32 banks on current architectures

→  $s$  must be odd

# Data Types and Bank Conflicts

- this has no conflicts if type of shared is 32-bits

```
__shared__ float shared[256];
float foo = shared[bi+threadIdx.x];
```

- smaller data types led to bank conflicts with older hardware

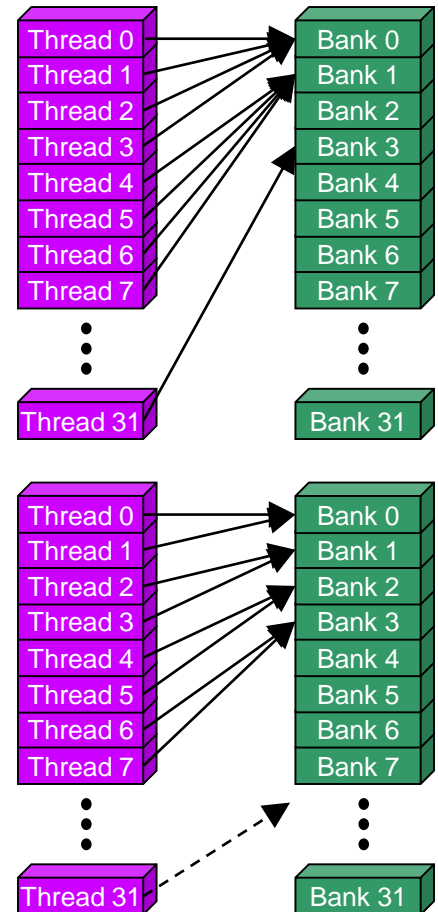

```
__shared__ char shared[256];
char foo = shared[bi+threadIdx.x];
```

➔ 4 way bank conflict

```
__shared__ short shared[256];
short foo = shared[bi+threadIdx.x];
```

➔ 2 way bank conflict

- solved by multicast feature on 2.x cards

# Structs and Bank Conflicts

- | struct assignments compile into as many memory accesses as there are struct members

```
struct vector { float x, y, z; };
__shared__ struct vector vectors[64];
struct vector v = vectors[bi+threadIdx.x];
```

- | this has no bank conflicts for vector
- | struct size is 3 words
- | 3 accesses per thread,  
implicit stride of 3  
(no common factor with 32)

# Structs and Bank Conflicts

- | struct assignments compile into as many memory accesses as there are struct members

```
struct myType { float f; char c; };  
__shared__ struct myType myTypes[64];  
struct myType m = myTypes[bi+threadIdx.x];
```

- | this has bank conflicts for myType
- | 2 accesses per thread
- | stride of 5 bytes

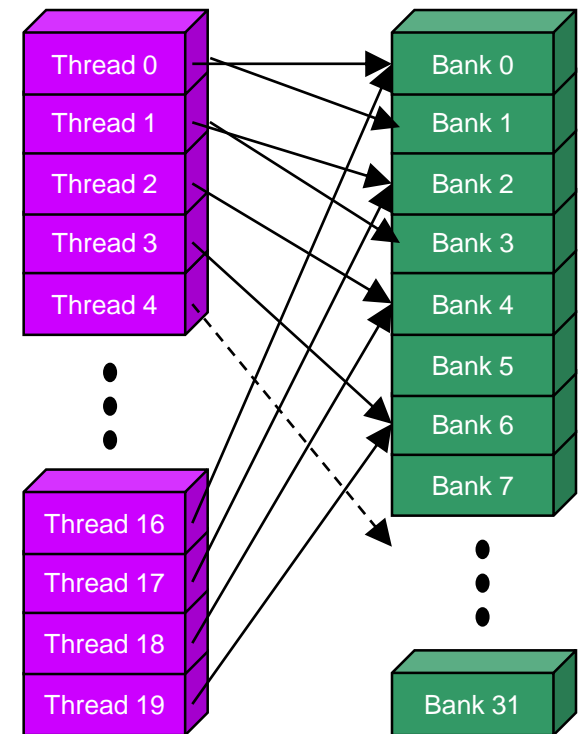

# Common Array Bank Conflict Patterns

- | 1D array
- | each thread loads 2 elements into shared memory

```
int tid = threadIdx.x;  
shared[2*tid] = global[2*tid];  
shared[2*tid+1] = global[2*tid+1];
```

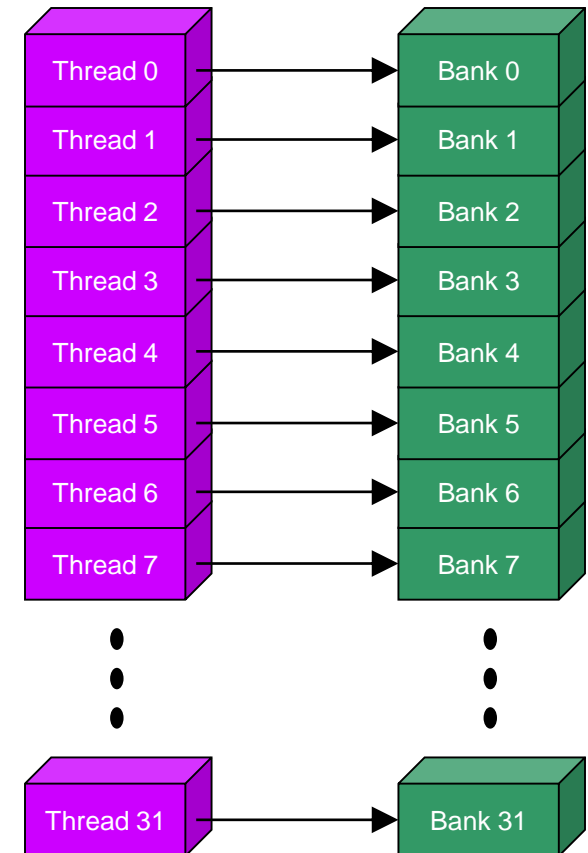

- | 2-way-interleaved loads result in 2-way bank conflicts
- | this makes sense for traditional CPU threads, locality in cache line usage, and reduced sharing traffic
- | not in shared memory usage where there is no cache line effects but banking effects

# Better Array Access Pattern

- | each thread loads one element in every consecutive group of `blockDim.x` elements.

```
shared[tid] = global[tid];  
shared[tid + blockDim.x] =  
    global[tid + blockDim.x];
```

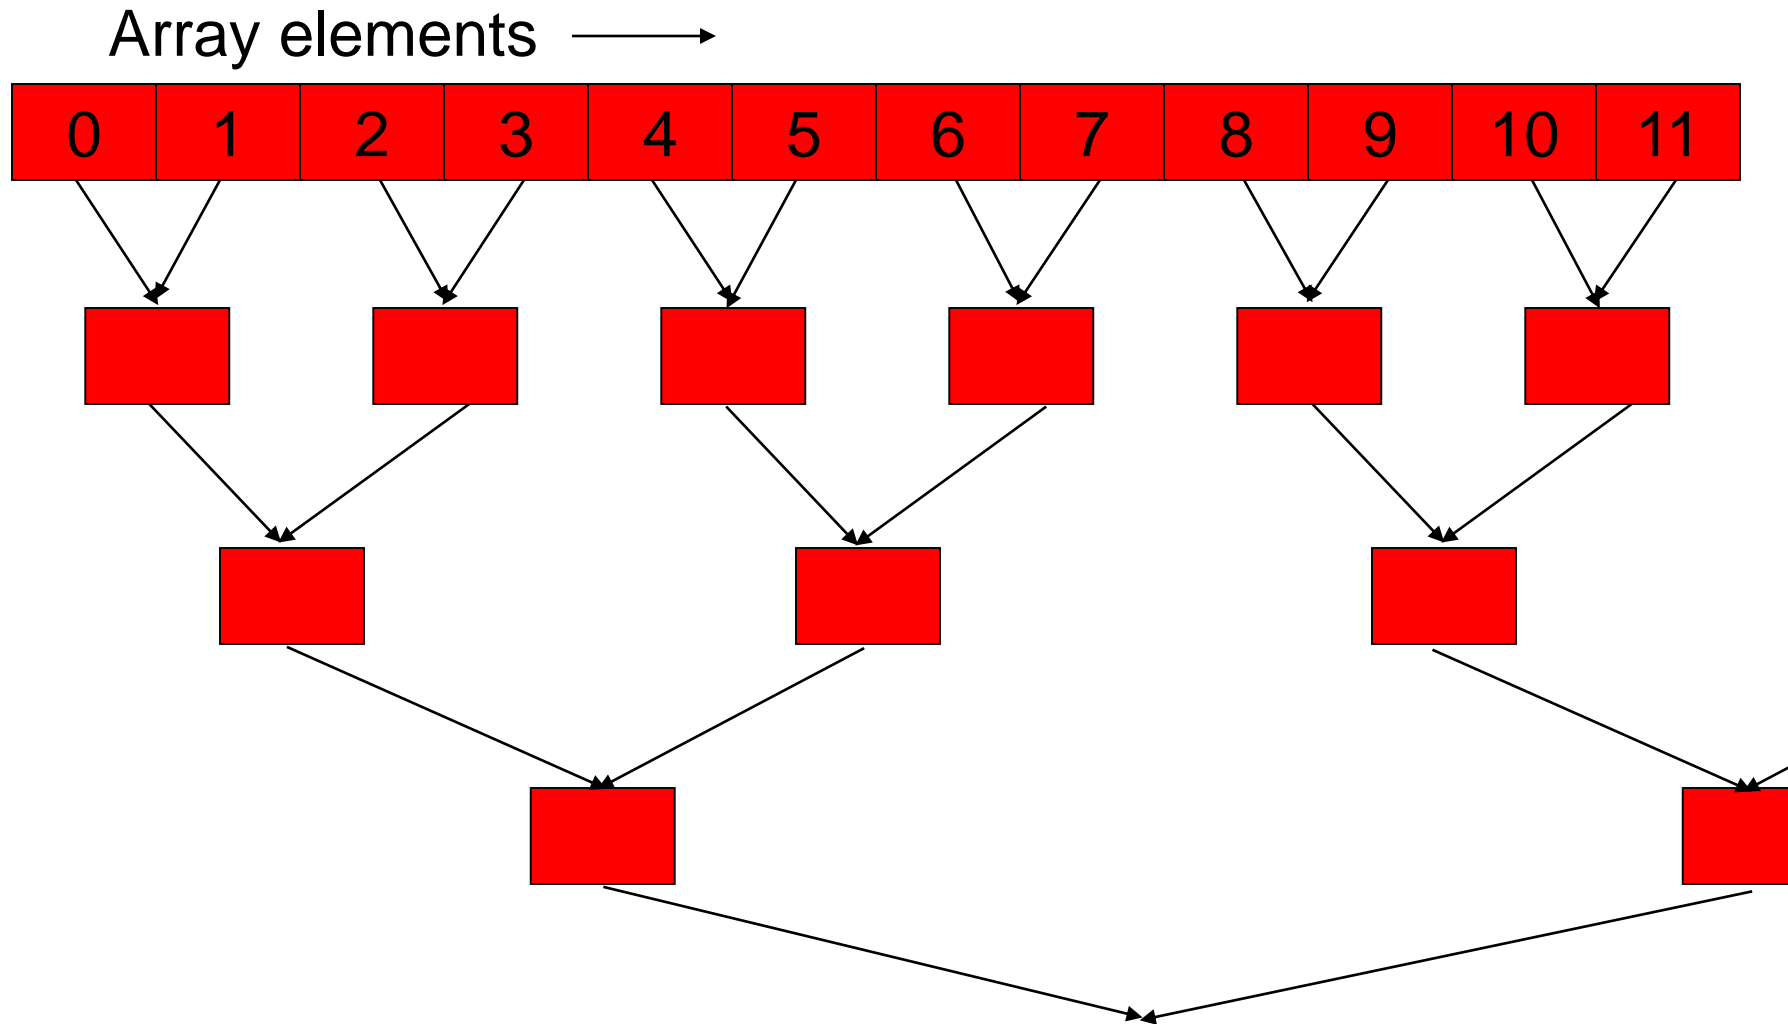

# Example: Vector Reduction

- | compute the sum, max, ... of all elements in an array

```
float sum=0;
float array[128];
for (int i=0; i<128; i++) {
    sum += array[i];
}
```

- | parallel implementation with logarithmic execution time

# Vector Reduction

# Vector Reduction with Bank Conflicts

# No Bank Conflicts

# Common Bank Conflict Patterns (2D)

- | operating on 2D array of floats in shared memory
  - | e.g. image processing
- | example:  
32x32 submatrix (subimage)
  - | each thread processes a row
  - | threads in a block access the elements in each column simultaneously
  - | example: row 1 in purple
    - 32-way bank conflicts  
rows all start at bank 0

0	1	2	3	4	5	6	7	...	31
0	1	2	3	4	5	6	7	...	31
0	1	2	3	4	5	6	7	...	31
0	1	2	3	4	5	6	7	...	31
0	1	2	3	4	5	6	7	...	31
0	1	2	3	4	5	6	7	...	31
0	1	2	3	4	5	6	7	...	31
0	1	2	3	4	5	6	7	...	31
⋮	⋮	⋮	⋮	⋮	⋮	⋮	⋮	⋮	⋮
0	1	2	3	4	5	6	7	...	31

# Common Bank Conflict Patterns (2D)

- | solution 1
  - | pad the rows
  - | add one float to the end of each row
  - | stride becomes odd

- | solution 2
  - | transpose before processing
  - | suffer bank conflicts during transpose
  - | but possibly save them later
  - | usually less writes than reads

# What about Matrix Multiplication?

- | all warps in a block access the same row of M  
➔ broadcast!
- | all warps in a block access neighboring elements in a row as the access walks through neighboring columns!

0	1	2	3	4	5	6	7	...	31
0	1	2	3	4	5	6	7	...	31
0	1	2	3	4	5	6	7	...	31
0	1	2	3	4	5	6	7	...	31
0	1	2	3	4	5	6	7	...	31
0	1	2	3	4	5	6	7	...	31
0	1	2	3	4	5	6	7	...	31
0	1	2	3	4	5	6	7	...	31
⋮	⋮	⋮	⋮	⋮	⋮	⋮	⋮	⋮	⋮
0	1	2	3	4	5	6	7	...	31

0	1	2	3	4	5	6	7	...	31
0	1	2	3	4	5	6	7	...	31
0	1	2	3	4	5	6	7	...	31
0	1	2	3	4	5	6	7	...	31
0	1	2	3	4	5	6	7	...	31
0	1	2	3	4	5	6	7	...	31
0	1	2	3	4	5	6	7	...	31
0	1	2	3	4	5	6	7	...	31
⋮	⋮	⋮	⋮	⋮	⋮	⋮	⋮	⋮	⋮
0	1	2	3	4	5	6	7	...	31

- | each block requires  $2 * WIDTH * WIDTH * 4$  bytes of shared memory
  - | for  $WIDTH = 32$ , each block requires 8KB
  - | depending on shared memory configuration 2 to 6 blocks can fit into the shared memory of an SMX
  
- | but:
  - | each SMX can only take 2048 threads (on K20X)
  - | each SMX can only take 2 blocks of 1024 threads each
  
- ➔ shared memory size is not a limitation for the Matrix Multiplication example
- ➔ For current GPUs its still not an issue

# Global Memory Access

- | device can access 32 bit, 64 bit, or 128 bit at once

```
__device__ type device[32];  
type data = device[tid];
```

- | compiles to a single load instruction if
  - | `sizeof(type)` is equal to 4, 8, or 16 and
  - | variables of type `type` must be aligned to `sizeof(type)` bytes (that is, have their address be a multiple of `sizeof(type)`).
- | alignment requirement is automatically fulfilled for built-in types like `float2` or `float4`

- | for structures, the size and alignment requirements can be enforced by the compiler using the alignment specifiers `__align__(8)` or `__align__(16)`

```
struct __align__(8) { float a; float b; };  
struct __align__(16) { float a; float b; float c;};
```

- | for structures larger than 16 bytes, the compiler generates several load instructions

- | use `__align__(16)` to minimize number of loads

```
struct __align__(16) { float a; float b; float c;  
                      float d; float e; };
```

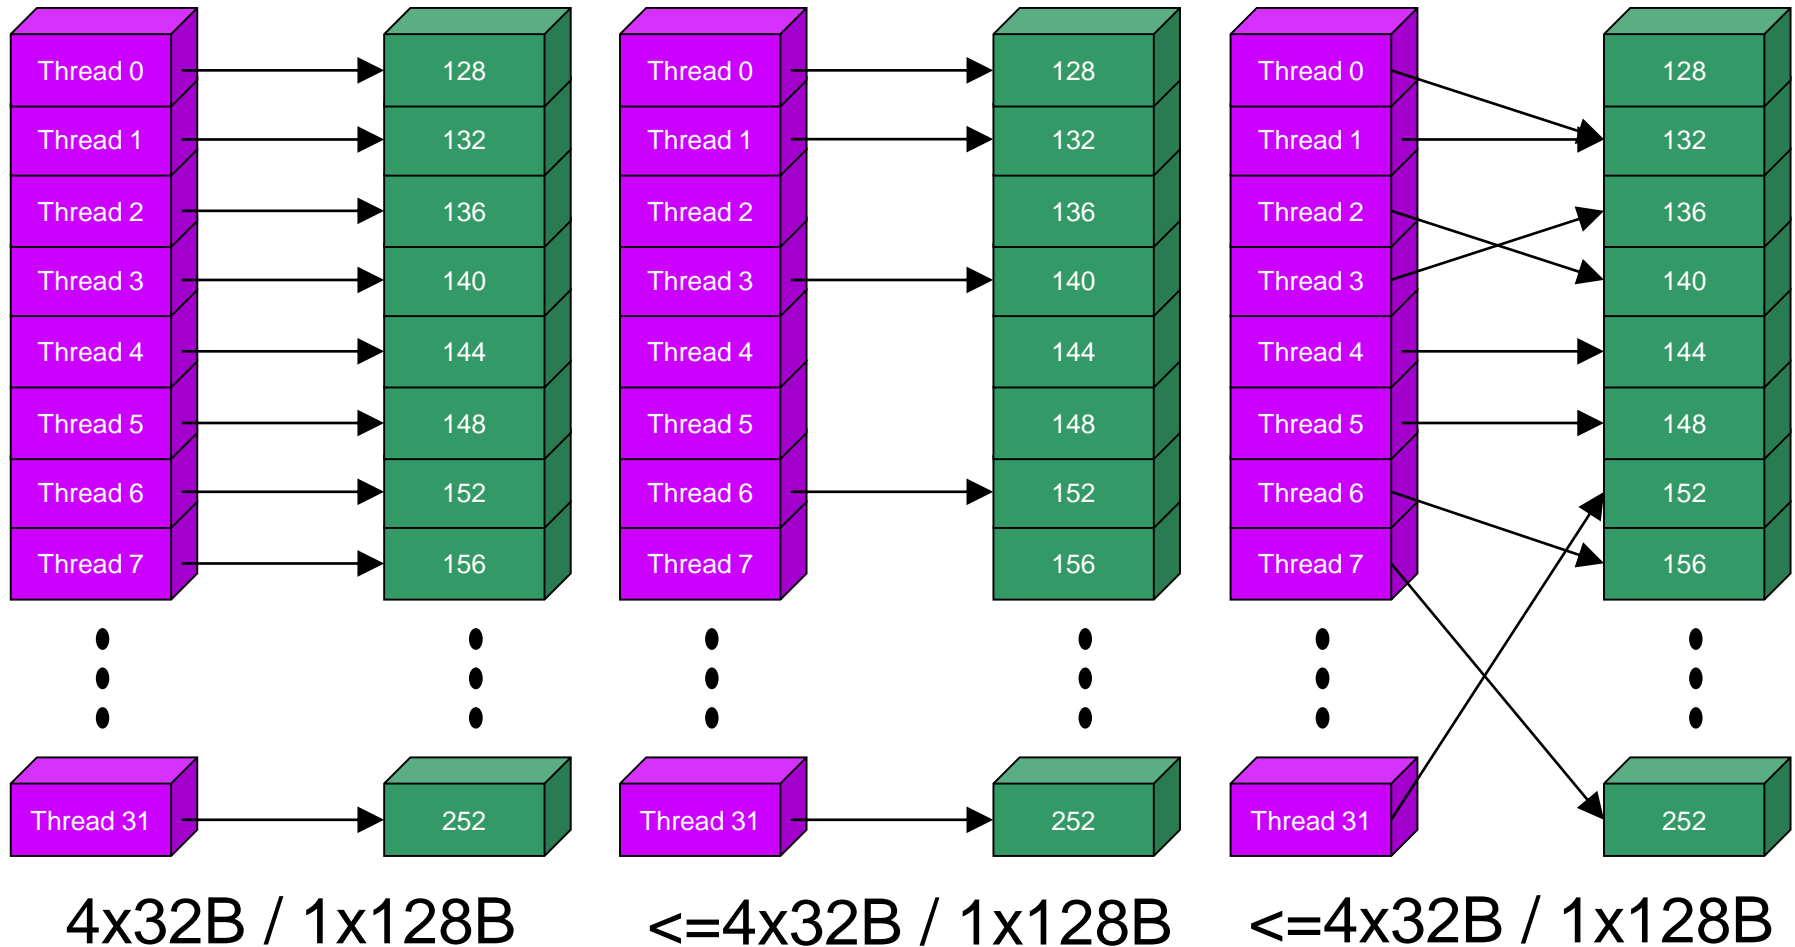

- | compiles into two 128-bit load instructions

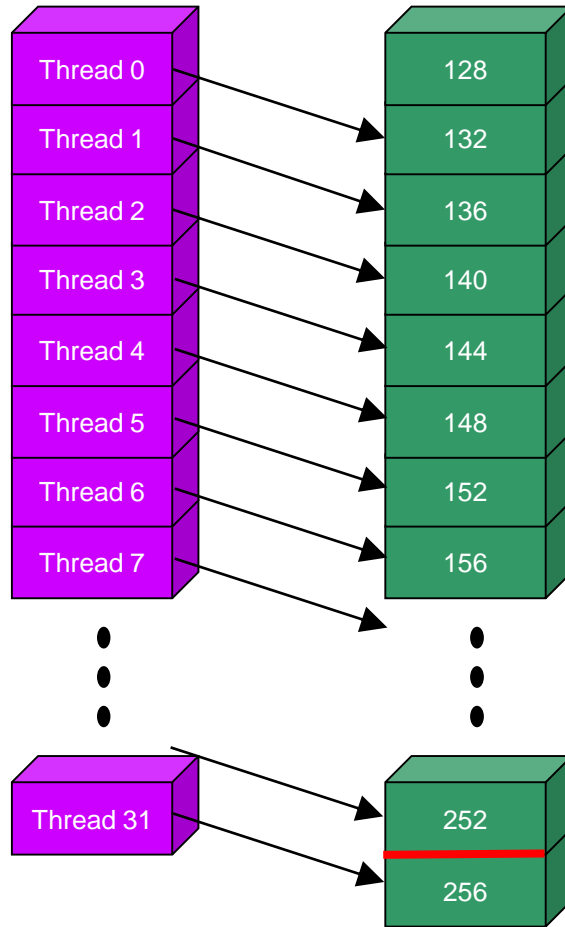

- | coalescing: combine loads from several threads in a warp into fewer transactions
- | will only consider compute capability 2.0 and up
  - | very strict rules on older hardware
- | global memory partitioned into continuous segments of 128 bytes
- | accessed via L1 and L2 cache which are aligned with these segments

- | L1 cache has a line size of 128 bytes
  - | → 1 cache line per 128 byte segment
  - | used per default for CC 2.x only
  
- | L2 cache has a line size of 32 bytes
  - | → 4 cache lines per 128 byte segment
  - | used per default for CC 3.x
  - | used per default for CC 5.x, no L1 present for write access
  
- | # transactions = # different cache lines accessed by a warp in a single load instruction

# Coalesced Global Memory Access

# Non-Coalesced Global Memory Access

5x32B / 2x128B

32x32B / 32x128B

- | L1 caching for global memory can be **disabled** at compile time for CC 2.x
- | L1 caching for global memory can be **enabled** at compile time for some CC 3.x GPUs
- | inline assembly allows to mix global memory accesses which are cached in L1 cache or only L2 cache in the same kernel **if and only if caching is enabled**
- | in general it is not recommended to change the default behavior

- | use load to hide load latency
  - | (non-dependent load ops only)
  - | use same thread to help hide own latency (ILP)

instead of

LD 0 (long latency)  
Dependent MATH 0  
LD 1 (long latency)  
Dependent MATH 1

use

LD 0 (long latency)  
LD 1 (long latency - hidden)  
MATH 0  
MATH 1

- | compiler handles this if enough non-dependent loads, math and registers are available
  - | that's why compiling a kernel might take a while

# ILP vs. TLP Example

- | assume that a kernel has
  - | 256-thread blocks
  - | 4 independent instructions for each global memory load in the thread program
  - | each thread uses 10 registers
  - | global loads take 200 cycles
  - ➔ 12 Blocks can run on each SMX 3.x
- | if a compiler can use one more register to change the dependence pattern so that 8 independent instructions exist for each global memory load
  - | Only 11 can run on each SMP
  - |  $200/(8*4) = 7$  warps needed to tolerate the memory latency
  - | 11 Blocks have 88 warps, performance can be actually higher!

*ILP has become a major factor in improving performance with 3.x and 5.x*

- | objectives
- | to understand the implications of control flow on
  - | branch divergence overhead
  - | SMP execution resource utilization
- | to learn better ways to write code with control flow
- | to understand compiler/HW predication designed to reduce the impact of control flow

# How Thread Blocks are Partitioned

- | thread blocks are partitioned into warps
  - | thread IDs within a warp are consecutive and increasing
  - | warp 0 starts with thread ID 0
- | partitioning is always the same
  - | thus you can use this knowledge in control flow
  - | the exact size of warps may change between hardware generations (but extremely unlikely!)
- | **DO NOT rely on any ordering between warps**
  - | if there are any dependencies between threads in different warps in the same block, you must use **\_\_syncthreads()** to get correct results

- | main performance concern with branching is divergence
  - | threads **within a single warp** take different paths
  - | different execution paths are serialized on all GPUs
  - | control paths taken by the threads in a warp are traversed one at a time until there is no more
  - | no penalty for divergence between warps, as long as all threads within a warp follow the same path

# Control Flow Instructions

- | common case: divergence when branch condition is a function of thread ID
- | example with divergence:
  - | `if (threadIdx.x > 2) { ... }`
  - | creates two different control paths for threads in a block
  - | branch granularity < warp size
  - | threads 0 and 1 follow different path than the rest of the threads in the first warp
- | example without divergence:
  - | `if (threadIdx.x / WARP_SIZE > 2) { ... }`
  - | also creates two different control paths for threads in a block
  - | branch granularity is a whole multiple of warp size
  - | all threads in any given warp follow the same path

# Parallel Reduction

- | given an array of values, “reduce” them to a single value in parallel
- | examples
  - | sum reduction: sum of all values in the array
  - | max reduction: maximum of all values in the array
- | typical parallel implementation:
  - | recursively halve the number of threads
  - | add two values per thread
  - ➔ takes  $\log(n)$  steps for  $n$  elements
  - ➔ requires  $n/2$  threads

# Vector Reduction Example

---

- | assume an in-place reduction using shared memory
  - | the original vector is in device global memory
  - | the shared memory used to hold a partial sum vector
  - | each iteration brings the partial sum vector closer to the final sum
  - | the final solution will be in element 0

# A Simple Implementation

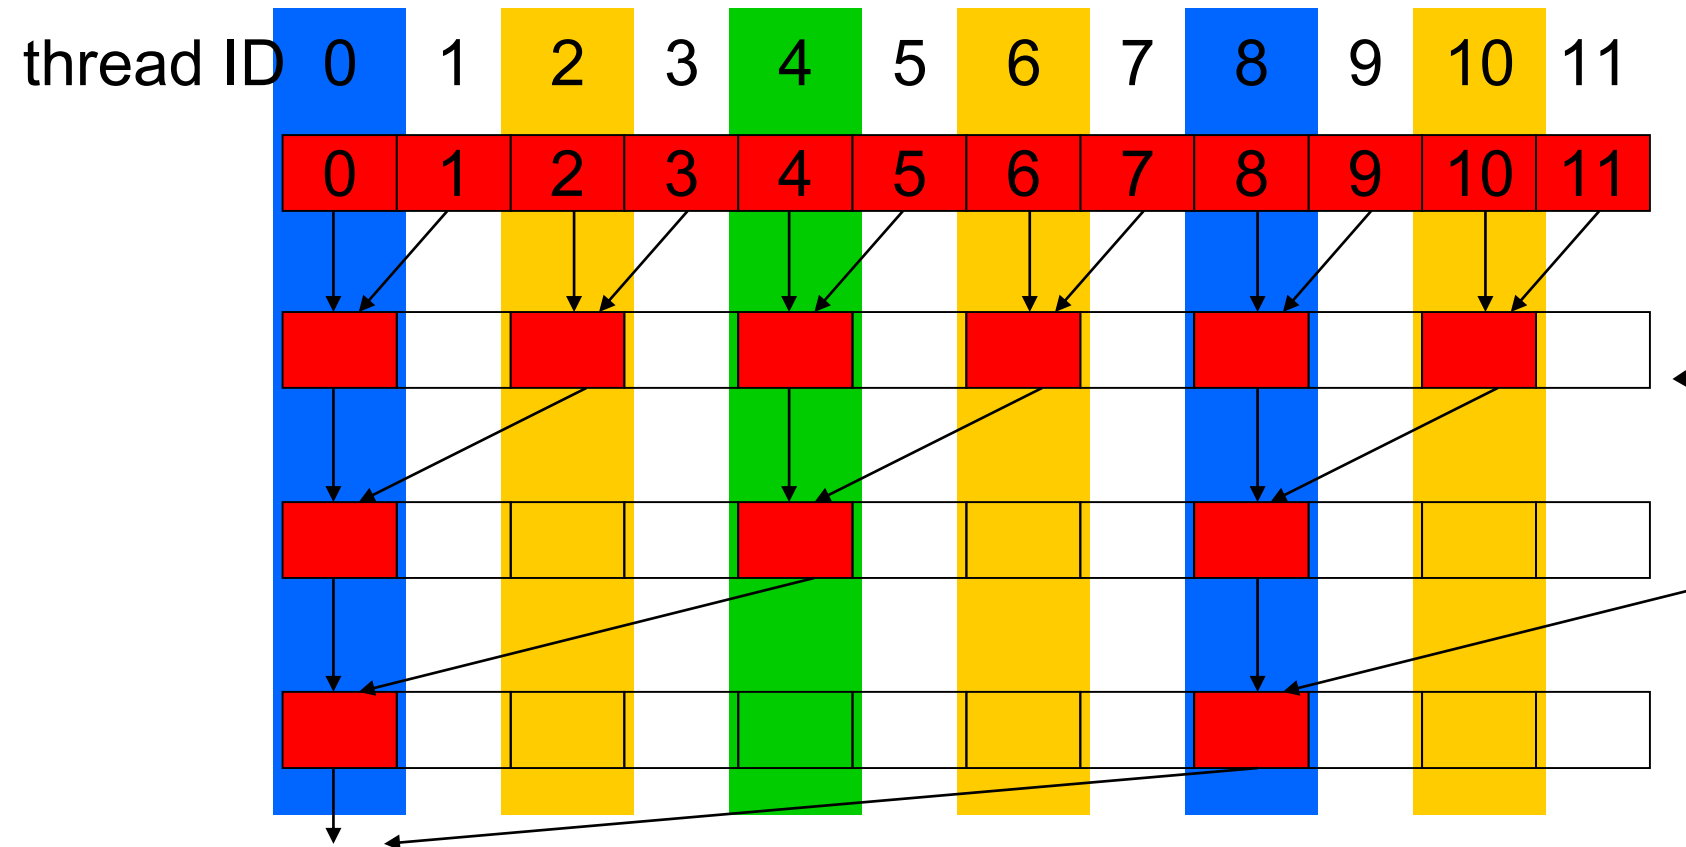

```
// create array and load data into shared memory
__shared__ float partialSum[]
// actual load omitted
[...]

unsigned int t = threadIdx.x;
unsigned int stride;
for (stride = 1; stride < blockDim.x; stride *= 2) {
    __syncthreads();
    if (t % (2*stride) == 0)
        partialSum[t] += partialSum[t+stride];
}
```

# Vector Reduction with Bank Conflicts

# Vector Reduction w/ Branch Divergence

- | in each iteration, two control flow paths will be sequentially traversed for each warp
  - | threads that perform addition and threads that do not
  - | threads that do not perform addition may cost extra cycles depending on the implementation of divergence
  
- | no more than half of threads will be executing at any time
  - | all odd index threads are disabled right from the beginning!
  - | on average, less than  $\frac{1}{4}$  of the threads will be activated for all warps over time
  - | after the 5<sup>th</sup> iteration, entire warps in each block will be disabled, poor resource utilization but no divergence
  - | this can go on for up to 4 more iterations ( $512/32=16=2^4$ ), where each iteration only has one thread activated until all warps retire

# Shortcomings of the Implementation

```
// create array and load data into shared memory
__shared__ float partialSum[]
// actual load omitted
[...]

unsigned int t = threadIdx.x;
unsigned int stride;
for (stride = 1; stride < blockDim.x; stride *= 2) {
    __syncthreads();
    // BAD interleaved decisions → divergence
    if (t % (2*stride) == 0)
        // BAD bank conflicts in memory access
        partialSum[t] += partialSum[t+stride];
}
```

# Better Implementation

```
// create array and load data into shared memory
__shared__ float partialSum[]
// actual load omitted
[...]

unsigned int t = threadIdx.x;
unsigned int stride;
for (stride = blockDim.x; stride > 1; ) {
    __syncthreads();
    stride >> 1;
    if (t < stride)
        partialSum[t] += partialSum[t+stride];
}
```

# No Divergence until $\leq 16$ Sub-Sums

- | now only the last 5 iterations will have divergence
- | entire warps will be shut down as iterations progress
  - | for a 512-thread block, 4 iterations to shut down all but one warp in each block
  - | better resource utilization, will likely retire warps and thus blocks faster
- | recall, no bank conflicts either

# (Dangerous?) Further Refinement

- | for last 6 loops only one warp active (i.e., tid' s 0..31)
  - | shared reads & writes SIMD synchronous within a warp
  - | skip `__syncthreads()` and unroll last iterations

```
// make sure that warp size is still 32
assert(WARP_SIZE == 32);
```

```
unsigned int tid = threadIdx.x;
for (unsigned int d = n>>1; d > 32; d >>= 1) {
    __syncthreads();
    if (tid < d)
        shared[tid] += shared[tid + d];
}
[...]
```

- | for last 6 loops only one warp active (i.e., tid' s 0..31)
  - | shared reads & writes SIMD synchronous within a warp
  - | skip `__syncthreads()` and unroll last iterations

[...]

```
__syncthreads();  
if (tid <= 32) { // unroll last 6 steps  
    shared[tid] += shared[tid + 32];  
    shared[tid] += shared[tid + 16];  
    shared[tid] += shared[tid + 8];  
    shared[tid] += shared[tid + 4];  
    shared[tid] += shared[tid + 2];  
    shared[tid] += shared[tid + 1];  
}
```

# Safe Further Refinement

- | for last 6 loops only one warp active (i.e., tid' s 0..31)
  - | threads in a single warp can communicate without shared memory using warp shuffling

[...]

```
__syncthreads();  
if (tid <= 32) { // unroll last 6 steps  
    float tmp = shared[tid] + shared[tid + 32];  
    tmp += __shfl_xor(tmp, 16);  
    tmp += __shfl_xor(tmp, 8);  
    tmp += __shfl_xor(tmp, 4);  
    tmp += __shfl_xor(tmp, 2);  
    tmp += __shfl_xor(tmp, 1);  
    shared[tid] = tmp;  
}
```

- | predicated statement  
    <p1> LDR r1, r2, 0
  - | if p1 is TRUE, instruction executes normally
  - | if p1 is FALSE, instruction treated as NOP

- | example

:	:
if (x == 10)	LDR r5, x
c = c + 1;	p1 <- r5 eq 10
:	<p1> LDR r1 <- C
	<p1> ADD r1, r1, 1
	<p1> STR r1 -> C
	:

# Predication Very Helpful for if-else

# Predication Very Helpful for if-else

- | extra instructions will be issued at code execution
- | there is, however, no branch divergence
- | scheduler can optimize execution order

```
      :  
      p1,p2 <- r5 eq 10  
<p1> inst 1 from B  
<p1> inst 2 from B  
<p1> :  
      :  
<p2> inst 1 from C  
<p2> inst 2 from C  
      :
```

```
      :  
      p1,p2 <- r5 eq 10  
<p1> inst 1 from B  
<p2> inst 1 from C  
<p1> inst 2 from B  
<p2> inst 2 from C  
<p1> :  
      :
```

# Instruction Predication

- | comparison instructions set condition codes (CC)
- | instructions can be predicated to write results only when CC meets criterion ( $CC \neq 0$ ,  $CC \geq 0$ , etc.)
- | compiler tries to predict if a branch condition is likely to produce many divergent warps
  - | if guaranteed not to diverge: only predicates if  $< 4$  instructions
  - | if not guaranteed: only predicates if  $< 7$  instructions
  - | may replace branches with instruction predication
- | **all predicated instructions take execution cycles**
  - | those with false conditions don't write their output or invoke memory loads and stores
  - | saves branch instructions, so can be cheaper than serializing divergent paths
